$$I = \frac{U}{R} \quad (2.2)$$

In the following we use probability theory to derive closed-form expressions for the fairness that is achieved among M contending stations. We tag station M and denote K_i the inter-transmissions of station $i = 1 \dots M - 1$ and let $K = \sum_{i=1}^{M-1} K_i$. The conditional probability $P[K = k|l]$ can be defined for $M \geq 2$ as

$$P[K = k|l] = P\left[\sum_{i=1}^{M-1} K_i = k \middle| l\right] \quad (2.3)$$

where the random variables K_i are the integers that satisfy

$$\sum_{j=1}^{K_i} b_i(j) \leq \sum_{j=1}^l b_M(j) \quad \text{and} \quad \sum_{j=1}^{K_i+1} b_i(j) > \sum_{j=1}^l b_M(j).$$

2.6 Theorem and Proof

We use the central limit theorem to derive the long-term fairness. In the sequel, we denote normal random variables $N(\mu, \sigma^2)$ where μ is the mean and σ^2 the variance.

For $M = 2$ we have from (2.3) that

$$P[K < k|l] = P\left[\sum_{j=1}^k b_1(j) > \sum_{j=1}^l b_2(j)\right]$$

and after expansion and some normalization this equals

$$= P\left[\frac{\sum_{j=1}^l b_2(j) - l\mu}{\sigma\sqrt{l}} - \frac{\sum_{j=1}^k b_1(j) - k\mu}{\sigma\sqrt{l}} < \frac{\mu(k-l)}{\sigma\sqrt{l}}\right].$$

Using the central limit theorem it follows that

$$P[K < k|l] \approx P\left[N(0, 1) - N\left(0, \frac{k}{l}\right) < \frac{\mu(k-l)}{\sigma\sqrt{l}}\right].$$

Since the normal distribution with zero mean is symmetric we can replace the subtraction of $N(0, k/l)$ by addition. Furthermore, the sum of two normal random variables $N(\mu_1, \sigma_1^2)$ and $N(\mu_2, \sigma_2^2)$ is normal with $N(\mu_1 + \mu_2, \sigma_1^2 + \sigma_2^2)$ such that

$$\mathbf{P}[K < k|l] \approx \mathbf{P}\left[N\left(0, \frac{k+l}{l}\right) < \frac{\mu(k-l)}{\sigma\sqrt{l}}\right].$$

Finally, we use that if X is $N(a\mu, a^2\sigma^2)$ then $Y = X/a$ is $N(\mu, \sigma^2)$ with $a^2 = (k+l)/l$ to standardize the result.

Th. ?? assumes i.i.d. random countdown values. It does, however, not make any assumption about their distribution.
